BACKGROUND

- Mortality rates in people living with HIV have declined due to effective antiretroviral treatment (ART) (1). Aging, coinfections, and comorbidities may drive further changes in mortality (2).
- We investigated recent patterns in mortality in the RESPOND cohort consortium to systematically monitor for unexpected trends and identify opportunities to reduce mortality.

METHODS

- The RESPOND cohort consortium was initiated in 2017 and includes over 30,000 people living with HIV from 17 cohorts across Europe and Australia.
- Prospective follow up from 2012 through 2019. Participants before 2017 enrolled retrospectively.
- Mortality classified by the Coding Causes of Death in HIV (CoDe) methodology (3).
- Age-standardized mortality rates were compared over time.
- Multivariable Poisson regression was used to investigate risk factors for all-cause mortality.

RESULTS

- 33,598 participants, 167,930 PYFU (median 4.8 years; IQR 3.1–8.0); 1700 (5.1%) died.
- Crude, all-cause mortality rate decreased over time.
- 2012–13: 13.0/1000 PYFU (95%CI 11.8–14.4)
- 2018–19: 8.6/1000 PYFU (95%CI 7.9–9.5)
- Median age at death increased over time:
- 2012–13: 52 (IQR 45–62); 2018–19: 56 (IQR 48–65)
- Highest cause-specific crude mortality rate was due to non-AIDS defining malignancy (NADM); see Table 1.
- Age-adjusted Poisson regression showed decreasing mortality from 2012–13 to 2018–19 for deaths due to NADM, AIDS, cardiovascular disease (CVD), liver disease, and other causes, but not unknown/missing (see Figure 2).
- In multivariable analysis including all risk factors where p<0.1 in univariable analysis (Figure 1), the strongest predictors of all-cause mortality were poor immunologic/virologic status (current CD4 ≤350 cells/mm³ + HIV viral load (VL) >200 cp/mL) vs. good immunologic/virologic status (CD4 ≥500 cells/mm³ + VL <200 cp/mL) and other modifiable risk factors.

In the RESPOND cohort from 2012 through 2019, cause-specific age-adjusted mortality rates declined. Immunologic/virologic status was the strongest predictor of mortality.

Figure 2: Age-standardized mortality rates (MR)

LIMITATIONS

- Many unknown/missing causes of death.
- Retrospective enrollment may lead to selection bias.

CONCLUSIONS

- Age-adjusted mortality rates due to specific causes declined from 2012–13 to 2018–19.
- Mortality due to NADM was greater than AIDS-, CVD-, or liver-related mortality.
- Median age at death has increased over time but is still relatively young compared to the background population.
- All-cause mortality was strongly associated with modifiable risk factors, especially immunologic/virologic status and chronic conditions, indicating areas for improvement.
